

The Vacuum Algorithm for solving the famous Traveling Salesperson Problem:

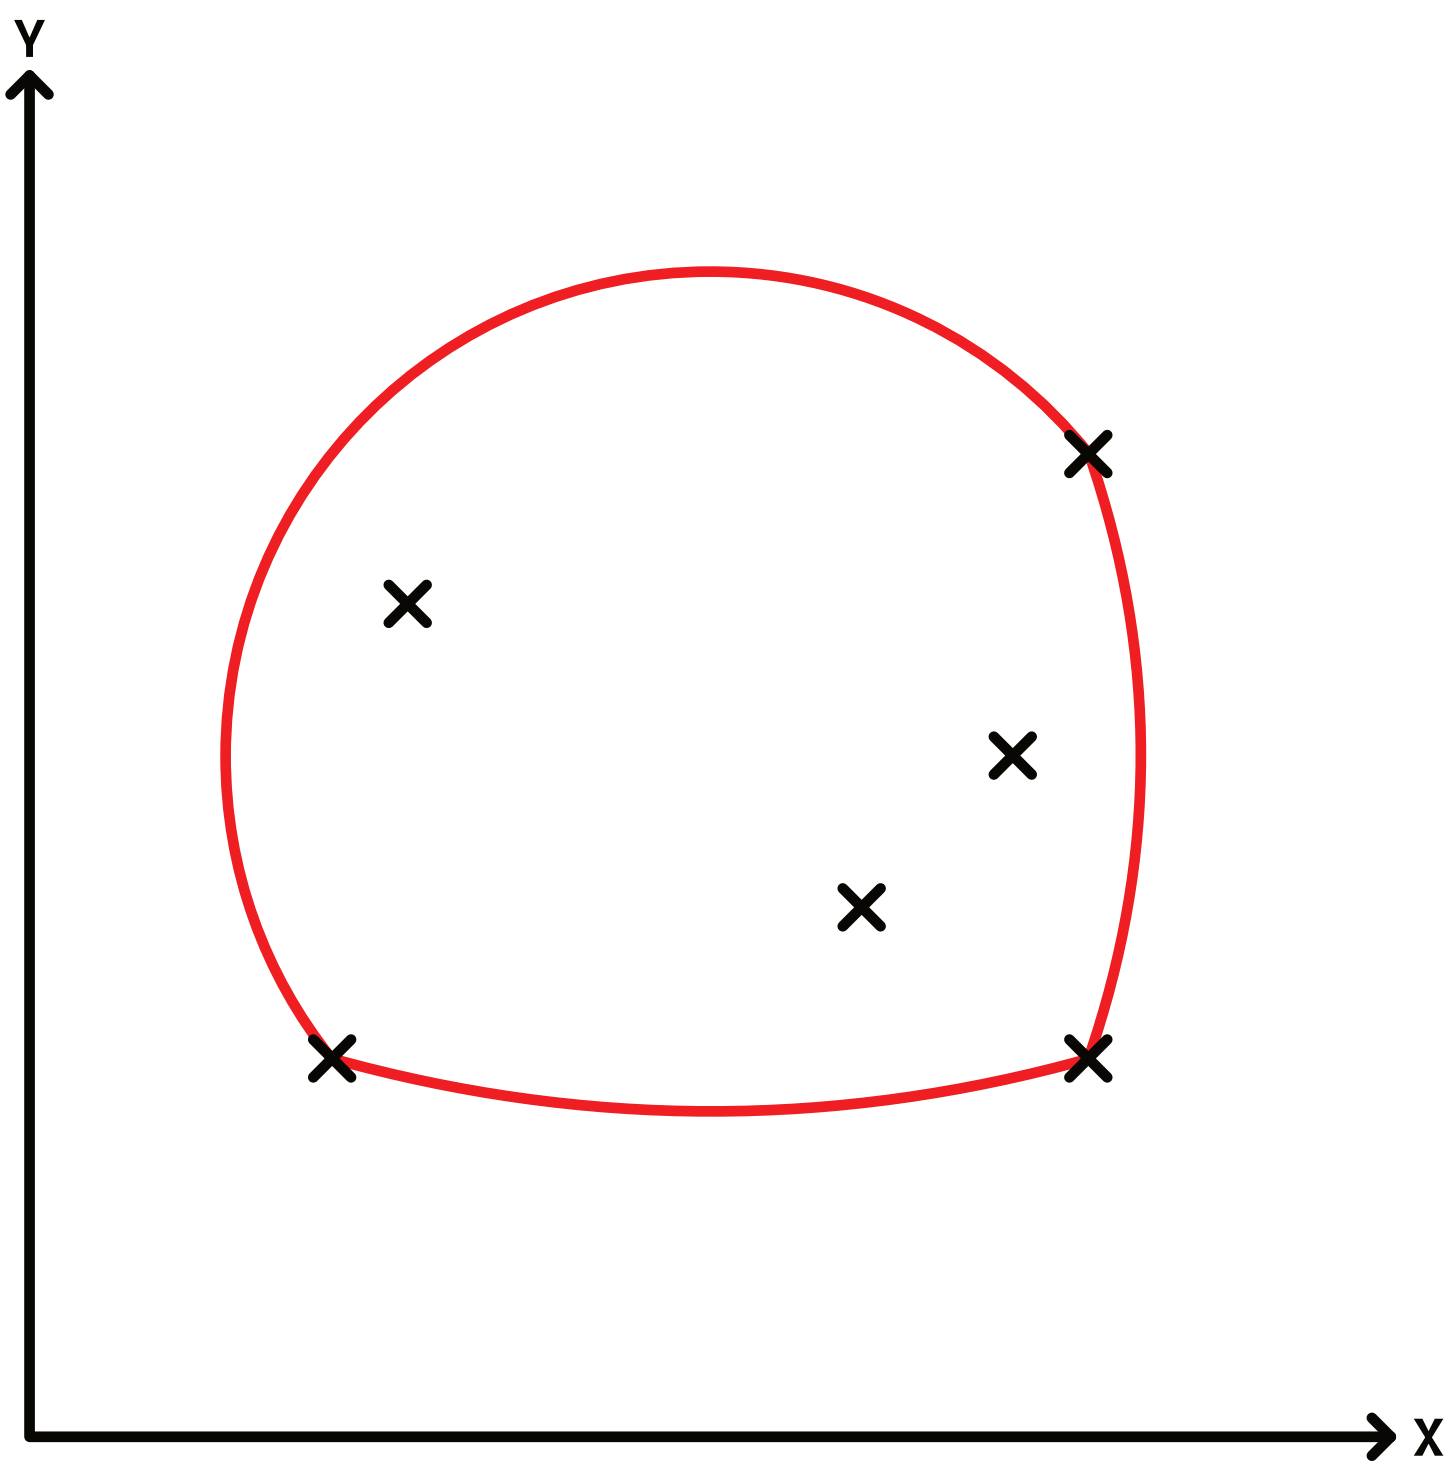

- 1. We consider a graph as having nodes that are firmly anchored and fixed in space according to their true-to-scale relationships to each other.**
- 2. We construct a virtual circular shape / virtual circle / virtual ellipse around the nodes so that all nodes of the graph are located within the circular shape, but not yet touching it.**
- 3. We then 'vacuum' the virtual circular shape, assuming that it behaves comparatively elastically – in other words, we deform it to the extent that it contracts to the narrowest degree around the nodes.**
- 4. We then abstract the overall connecting lines between the nodes to straight lines.**
